Summary

The vision of Interfere is simple: What if we used high quality scientific models to benchmark causal prediction tools? Randomized experimental data and counterfactuals are essential for testing methods that attempt to infer causal relationships from data, but obtaining such datasets can be expensive and difficult. Mechanistic models are commonly developed to simulate scenarios and predict the response of systems to interventions across economics, neuroscience, ecology, systems biology and other areas (Baker et al., 2018; Banks et al., 2017; Brayton et al., 2014; Izhikevich & Edelman, 2008). Because these models are painstakingly calibrated with the real world, they have the ability to generate diverse and complex synthetic counterfactual data that are characteristic of the real processes they emulate. Interfere offers the first steps towards this vision by combining (1) a general interface for simulating the effect of interventions on dynamic simulation models, (2) a suite of predictive methods and cross validation tools, and (3) an extensible benchmark data set of dynamic counterfactual scenarios see Figure 1.

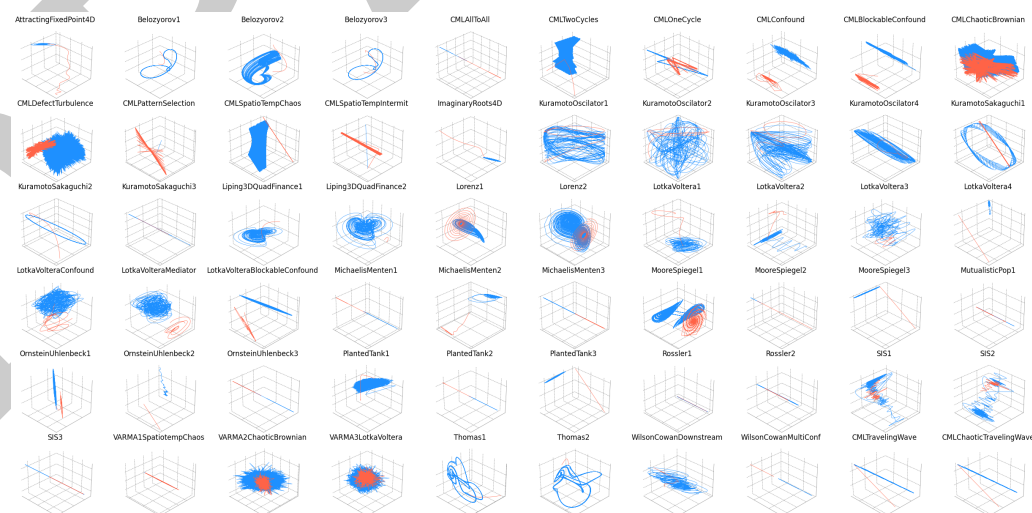

Figure 1: Three-dimensional trajectories of sixty scenarios simulated with the Interfere package. The models simulated here are either differential equations or discrete time difference equations. For each system, the trajectory in blue represents the natural behavior of the system and the red depicts how the system responds to a specified intervention. Many of the models pictured have more than three dimensions (in such cases, only the three dimensions of the trajectory with the highest variance are shown). These sixty scenarios make up the [Interfere Benchmark 1.1.1](#) for intervention response prediction which is available online for download.

Statement of Need

Over the past twenty years, the scientific community has experienced the emergence of multiple frameworks for identifying causal relationships in observational data (Imbens & Rubin, 2015; Pearl, 2009; Wieczorek & Roth, 2019). The most influential frameworks are probabilistic and, while it is not a necessary condition for identifying causality, historically a linear relationship has often been assumed. However, when attempting to anticipate the response of complex systems in the medium and long term, a linear approximation of the dynamics is typically insufficient. Therefore, researchers have increasingly begun to employ non-linear techniques for causal analysis (e.g. Runge, 2022). Still, there are relatively few techniques that are able to fit causal dynamic nonlinear models to data. Because of this, we see an opportunity to bring together the insights from recent advancements in causal inference with historical work in dynamic modeling and simulation.

In order to facilitate this cross pollination, we focus on a key causal problem — predicting how a complex system responds to a previously unobserved intervention — and designed the Interfere package for benchmarking tools aimed at intervention response prediction. The dynamic models contained in Interfere present challenges for causal inference that can likely only be addressed with the incorporation of mechanistic assumptions alongside probabilistic tools. As such, the Interfere package presents an opportunity for cross pollination between the causal inference community and the modeling and simulation community.

Usage

The Interfere package is designed around four tasks: (1) simulation, (2) intervention, (3) forecasting method optimization and (4) intervention response prediction. The following section will describe each task in detail alongside example code.

1. Simulation.

The models implemented in the Interfere package are mainly stochastic differential equations (e.g. $d\mathbf{X} = \mathbf{A}\mathbf{X} + d\mathbf{W}$) simulated with the users choice of Ito's method or SR1, (a strong Runge-Kutta method, see (Rößler, 2010)) or stochastic difference equations (e.g. $x[n+1] = 0.25x[n] - 0.5x[n-1]$), simulated via initial conditions and stepping forward in time. Each dynamic model class included in the Interfere package has a simulate method. To run a simulation, the package requires an array of equally spaced time values and an array containing initial conditions or historic observations. For example, the following code block produces the trajectories plotted in Figure 2:

```
import numpy as np
import interfere
import optuna

# Set up simulation parameters
initial_cond = np.random.rand(3)
t_train = np.arange(0, 10, 0.05)
dynamics = interfere.dynamics.Belozorov3DQuad(sigma=0.5)

# Generate trajectory
sim_states = dynamics.simulate(t_train, initial_cond)
```

Figure 2: Simulation of System: The natural, uninterrupted evolution of the quadratic Belozyorov system (Belozyorov, 2015) with the addition of a small amount of stochastic noise simulated using the Interfere package.

2. Intervention

Next, we can take exogenous control of x by pinning it to $\sin(t)$ and simulate the response of y . The resulting simulation reveals how the behavior of the system is altered by this particular intervention. See Figure 3 to see how the quadratic Belozyorov system (Belozyorov, 2015) responds to this intervention.

```
# Time points for the intervention simulation
test_t = np.arange(t_train[-1], 15, 0.05)

# Intervention initialization
intervention = interfere.SignalIntervention(iv_idx=1, signals=np.sin)

# Simulate intervention
interv_states = dynamics.simulate(
    test_t,
    prior_states=sim_states,
    intervention=intervention,
)
```

Figure 3: System trajectory with intervention: The figure above demonstrates the effect that taking exogenous control of $x(t)$ by via $\text{do}(x(t) = \sin(t))$ has on y . The intervention (black) and response (blue), depict a clear departure from the natural evolution behavior of the system.

3. Optimization

Interfere offers tools to optimize forecasting methods for time series prediction. By using Interfere's cross validation objective function along with a hyperparameter optimizer such as Optuna (Akiba et al., 2019), it is possible to compare hyperparameter settings on multiple folds of time series data. To simplify this process, every Interfere forecasting method comes with sensible preset hyperparameter ranges for the optimizer to explore. Using the cross validation objective function for hyperparameter optimization is demonstrated in the following code block.

```
# Select the SINDy method for hyperparameter optimization.
method_type = interfere.SINDy

# Create an objective function that aims to minimize cross validation error
# over different hyper parameter configurations for SINDy
cv_obj = interfere.CrossValObjective(
    method_type=method_type,
    data=sim_states,
    times=t_train,
    train_window_percent=0.3,
    num_folds=5,
    exog_idx=intervention.iv_idx,
)

# Run the study using optuna.
study = optuna.create_study()
study.optimize(cv_obj, n_trials=25)

# Collect the best hyperparameters into a dictionary.
best_param_dict = study.best_params
```

4. Intervention Response Prediction

Using the best parameters from the hyperparameter optimization run, we can fit the forecasting method to all the data that occurred prior to the intervention, treating the states we plan to manipulate as exogenous. This way, the method expects to be given exogenous data about the intervention variable(s). After fitting to the unperturbed system, we forecast the intervention response by treating the desired intervention as an exogenous input signal applied during forecasting. Figure 4 depicts the optimized model's ability to forecast the intervention response.

```
# Initialize SINDy with the best performing parameters.
method = interfere.SINDy(**study.best_params)

# Use an intervention helper function to split the pre-intervention data
# into endogenous and exogenous columns.
Y_endog, Y_exog = intervention.split_exog(sim_states)

# Fit SINDy to the pre-intervention data.
method.fit(t_train, Y_endog, Y_exog)

# Use the inherited interfere.ForecastingMethod.simulate() method
# To simulate intervention response using SINDy
pred_traj = method.simulate(
    test_t, prior_states=sim_states, intervention=intervention
)
```

Figure 4: Forecasting Intervention Response: Example of forecasting the response of the Belozyorov system to a sinusoidal intervention. Here, the intervention consists of taking exogenous control of $x(t)$ (black). The ground truth response, $y(t)$ for $t > 10$ is plotted in blue. Here, an equation discovery algorithm, SINDy, (Brunton et al., 2016) is fit to the data that occurs prior to the intervention and makes an attempt to predict the intervention response (red curve). However, not all intervention responses can be so accurately predicted. See the bottom left of Figure 5 for a failed forecast scenario.

Primary Contributions

The Interfere package provides three primary contributions. (1) Dynamically diverse counterfactuals at scale, (2) cross disciplinary forecast methods, and (3)

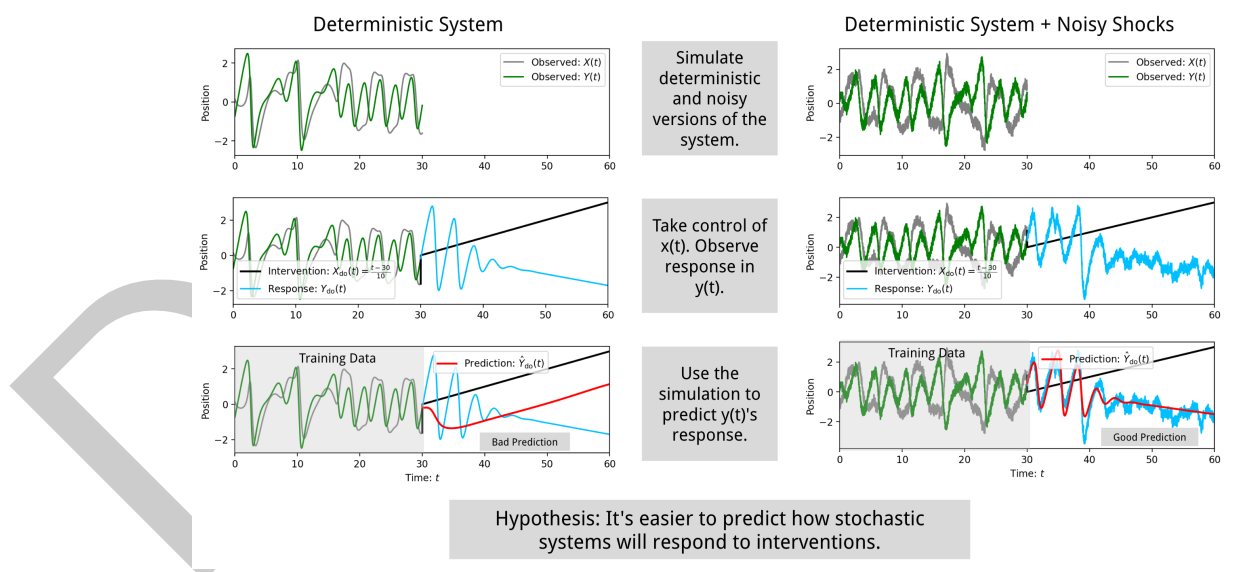

Figure 5: Example experimental setup possible with Interfere: Comparing intervention response prediction for deterministic and stochastic versions of the same system. Can stochasticity help reveal associations between variables?

1. Dynamically Diverse Counterfactuals at Scale

The “dynamics” submodule in the Interfere package contains over fifty dynamic models. It contains a mix of linear, nonlinear, chaotic, continuous time, discrete time, stochastic, and deterministic models. The models come from a variety of disciplines including economics, finance, ecology, biology, neuroscience and public health. Each model inherits the from the Interfere BaseDynamics type and gains the ability to take exogenous control of any observed

state and to add measurement noise. Most models also gain the ability to make any observed state stochastic where magnitude of stochasticity can be controlled by a simple scalar parameter or fine tuned with a covariance matrix.

Because of the difficulty of building models of complex systems, predictive methods for complex dynamics are typically benchmarked on less than ten dynamical systems (Brunton et al., 2016; Challu et al., 2023; Pathak et al., 2018; Prasse & Van Mieghem, 2022; Vlachas et al., 2020). As such, Interfere offers a clear improvement over current benchmarking methods for prediction in complex dynamics.

Most importantly, Interfere is built around interventions: the ability to take exogenous control of the state of a complex system and observe the response. Imbuing scientific models with general exogenous control is no small feat because models can be complex and are implemented in a variety of ways. Thus Interfere offers the ability to produce multiple complex dynamic *counterfactual scenarios* at scale. This unique feature enables large scale evaluation of dynamic causal prediction methods—tested against systems with properties of interest to scientists.

2. Cross Disciplinary Forecast Methods

A second contribution of Interfere is the integration of dynamic *forecasting* methodologies from deep learning, applied mathematics and social science. The Interfere “ForecastingMethod” class is expressive enough to describe, fit and predict with multivariate dynamic models and intervene on the states of the models during prediction. This cross disciplinary mix of techniques affords new insights into the problem of intervention response prediction.

3. Comprehensive and Extensible Benchmarking

The third major contribution of Interfere is the collection of dynamic scenarios organized into the [Interfere Benchmark](#). The Interfere Benchmark is a comprehensive and extensible set of dynamic scenarios that are conveniently available for testing methods that predict the effects of interventions. The benchmark set contains 60 intervention response scenarios for testing, each simulated with different levels of stochastic noise. Each scenario is housed in a JSON file, complete with full metadata annotation, documentation, versioning and commit hashes marking the commit of Interfere that was used to generate the data. The scenarios were carefully calibrated and some systems were exposed to exogenous input to ensure that none of the dynamic scenarios in the benchmark settle into a steady state. Additionally, all interventions were chosen in a manner such that the response of the target variable is a significant departure from its previous behavior.

Thus, the Interfere package poses the problem of predicting intervention response — a highly applicable question, to the broader community and thereby facilitates future progress towards correctly anticipating how complex systems will respond in new, never before seen scenarios.

Related Software and Mathematical Foundations

Predictive Methods

The Interfere package draws extensively from the Nixtla open source ecosystem for time series forecasting. Nixtla's NeuralForecast proves two of the methods that are integrated with Interfere's interface, LSTM and NHITS, while StatsForecast provides one of the methods, ARIMA (Azul Garza, 2022; Olivares et al., 2022). Nixtla also provided the inspiration for the cross validation and hyperparameter optimization workflow. Interfere also integrates with predictive methods from the PySINDy (Kaptanoglu et al., 2022) and StatsModels (Seabold & Perktold, 2010) packages. Interfere also includes ResComp, an additional reservoir computing method for global forecasts from (Harding et al., 2024). Hyperparameter optimization is designed around the Optuna framework (Akiba et al., 2019).

While other forecasting methods exist, integrating a method with Interfere requires that the method is capable of (1) multivariate endogenous dynamic forecasting, (2) support for exogenous variables, and (3) support for flexible length forecast windows or recursive predictions. It can be challenging to find methods that support all of these requirements and are also robust under a range of input training data. For this reason, additional forecasting methods are needed to address the problem of intervention response prediction.

Dynamic Models

The table below list the dynamic models that are currently implemented in the Interfere package, plus attributions. These dynamic models in were implemented directly from mathematical descriptions except for two, “Hodgkin Huxley Pyclustering” and “Stuart Landau Kuramoto” which adapt existing simulations from the PyClustering package (Novikov, 2019).

Dynamic Model Class	Description and Source	Properties
Arithmetic Brownian Motion	Brownian motion with linear drift and constant diffusion (Øksendal, 2005)	Stochastic, Linear
Coupled Logistic Map	Discrete-time logistic map with spatial coupling (Lloyd, 1995)	Nonlinear, Chaotic
Stochastic Coupled Map Lattice	Coupled map lattice with stochastic noise (Kaneko, 1991)	Nonlinear, Stochastic, Chaotic
Michaelis Menten	Model for enzyme kinetics and biochemical reaction networks (Srinivasan, 2022)	Nonlinear, Stochastic
Lotka Volterra SDE	Stochastic Lotka-Volterra predator-prey model (Hening & Nguyen, 2018)	Nonlinear, Stochastic
Kuramoto	Coupled oscillator model to study synchronization (Rodrigues et al., 2016)	Nonlinear, Stochastic
Kuramoto Sakaguchi	Kuramoto model variant with phase frustration (Sakaguchi & Kuramoto, 1986)	Nonlinear, Stochastic
Hodgkin Huxley Pyclustering	Neuron action-potential dynamics based on Hodgkin-Huxley equations (Hodgkin & Huxley, 1952)	Nonlinear
Stuart Landau Kuramoto	Coupled oscillators with amplitude-phase dynamics (Cliff et al., 2023)	Nonlinear, Stochastic
Mutualistic Population	Dynamics of interacting mutualistic species (Prasse & Van Mieghem, 2022)	Nonlinear
Ornstein Uhlenbeck	Mean-reverting stochastic differential equation (Gardiner, 2009)	Stochastic, Linear
Belozyorov 3D Quad	3-dimensional quadratic chaotic system (Belozyorov, 2015)	Nonlinear, Chaotic
Liping 3D Quad Finance	Chaotic dynamics applied in financial modeling (Liping et al., 2021)	Nonlinear, Chaotic
Lorenz	Classic chaotic system describing atmospheric convection (Lorenz, 2017)	Nonlinear, Chaotic
Rossler	Simplified 3D chaotic attractor system (Rössler, 1976)	Nonlinear, Chaotic
Thomas	Chaotic attractor with simple structure and rich dynamics (Thomas, 1999)	Nonlinear, Chaotic
Damped Oscillator	Harmonic oscillator with damping and noise (Classical linear model)	Linear, Stochastic

Dynamic Model Class	Description and Source	Properties
SIS	Epidemiological model (Susceptible-Infected-Susceptible) (Prasse & Van Mieghem, 2022)	Nonlinear, Stochastic
VARMA Dynamics	Vector AutoRegressive Moving Average for time series modeling (Hamilton, 2020)	Linear, Stochastic
Wilson Cowan	Neural mass model for neuronal population dynamics (Wilson & Cowan, 1972)	Nonlinear
Geometric Brownian Motion	Stochastic model widely used in financial mathematics (Black & Scholes, 1973)	Nonlinear, Stochastic
Planted Tank Nitrogen Cycle	Biochemical cycle modeling nitrogen transformation in aquatic systems (Fazio & Jannelli, 2006)	Nonlinear
Generative Forecaster	Predictive forecasting models trained on simulation, then used to generate data (Written for Interfere)	Stochastic
Standard Normal Noise	IID noise from standard normal distribution (Cliff et al., 2023)	Stochastic
Standard Cauchy Noise	IID noise from standard Cauchy distribution (Cliff et al., 2023)	Stochastic
Standard Exponential Noise	IID noise from standard exponential distribution (Cliff et al., 2023)	Stochastic
Standard Gamma Noise	IID noise from standard gamma distribution (Cliff et al., 2023)	Stochastic
Standard T Noise	IID noise from Student's t-distribution (Cliff et al., 2023)	Stochastic
